INTRODUCTION

Dr. Irina Barbolina, Technical Director, Technical Service Consultants Ltd., approached Campden BRI to evaluate the performance of the Pathogenic *Listeria* Detection Kit (SwabSURE-Listeria).

The protocol used to evaluate the SwabSURE-Listeria kit was provided by Technical Service Consultants Ltd. This study determined the specificity and sensitivity of the test.

MATERIALS AND METHODS

The SwabSURE-Listeria kit was used in accordance with the instructions provided by Technical Service Consultants Ltd. (see Appendix). Each test consisted of a foam swab to sample the chosen site (Appendix, Fig. 1). This swab is subsequently inserted into a second tube containing a selective diagnostic medium for the growth of *Listeria* species; antibiotics that restrict or inhibit the growth of non-target organisms, and a chromogenic compound for the detection of the two main pathogenic *Listeria* species (*L. monocytogenes* and *L. ivanovii*). The presence of *L. monocytogenes* and/or *L. ivanovii* at the concentration of ≥ 1 cell/sample results in colour change of the medium from straw-yellow to turquoise-blue (Appendix, Fig. 2). Each test was incubated at 37°C and results observed and recorded at 24h and 48h.

1) Specificity (inclusivity)

The specificity (inclusivity) of the SwabSURE-Listeria kit was determined using 51 strains of pathogenic *Listeria* spp. (40 *L. monocytogenes* and 11 *L. ivanovii*). The strains used are presented in Table 1. Each strain was grown in Tryptone Soya broth (TSB) and diluted to give different concentration of each strain between approximately 10 and 100 cfu/sample. Two levels (~1-50 and ~50-100 cfu/swab) to cover the range of concentrations requested by the client were tested. Duplicate swabs were inoculated with diluted culture to achieve the correct

concentration per swab. A swab inoculated with sterile medium only (negative control) was also tested. The swabs were processed in accordance with the manufacturer's instructions.

2) Specificity (exclusivity)

The specificity (exclusivity) of the SwabSURE-Listeria kit was determined using 50 strains of non-target organisms. The strains used are presented in Table 2. Each of the 50 strains of non-target organisms were cultured in appropriate media depending on their specific growth requirements. The media and incubation temperatures used were; TSB 37°C (all *Listeria* strains), Nutrient broth (NB) 30°C (*Bacillus* spp., *Micrococcus* spp. and *Pseudomonas* spp.), NB 37°C (*Staphylococcus* spp., *Enterococcus* spp. and *Rhodococcus equi*) and members of the Enterobacteriaceae (e.g. *Citrobacter* spp., *Enterobacter* spp., *Proteus* spp. and *Salmonella*), NB 25°C *Brochothrix thermosphacta*, deMan Rogosa Sharpe broth (MRSB) *Lactobacillus* spp. (microaerophilic atmosphere) and *Pediococcus* spp. (aerobic atmosphere) and Malt Extract broth (yeast strains).

All of the strains were diluted to give a final concentration of approximately 100-1000 cfu per swab. Each strain was initially diluted to a concentration of ~1,000 cfu per swab which represented the highest level (worst case) specified by the client. Swabs were processed in accordance with the manufacturer's instructions. The results from this study were recorded along with any observations. Any strains giving positive results (false positive) at the high contamination level were repeated at a lower concentration of ~100 cfu per swab.

3) Sensitivity

The sensitivity of the SwabSURE-Listeria kit was determined using 10 strains of pathogenic *Listeria* spp. (6 *L. monocytogenes* and 4 *L. ivanovii*). The strains used are presented in Table 3. Each strain was grown in tryptone soya broth (TSB) and diluted to give different concentration of each strain between 1 and 100,000 cfu/swab. A total of 4 different levels were tested (1-10, 100-1000,

1000-10,000 and 10,000-100,000 cfu/swab) to cover the range of concentrations requested by the client. Duplicate swabs were inoculated with diluted culture to achieve the correct concentration per swab. A swab inoculated with sterile medium only (negative control) was also tested.

The swabs were processed in accordance with the manufacturer's instructions. The results (e.g. medium colour after 24h and 48h incubation) were recorded along with any other observations during the study.

RESULTS

The specificity results obtained with the SwabSURE-Listeria kit are presented in Table 4 (inclusivity) and Table 5 (exclusivity). The test successfully detected all of the *L. monocytogenes* strains within 48h. Fifteen strains (38%) yielded an earlier (24h) positive result with at least one of the contamination levels used, although only one swab per duplicate was positive at 24h with three of these strains. The test can therefore provide an earlier indication of *Listeria monocytogenes* contamination if sufficient cells are present, although to confirm the presence of *L. monocytogenes* the test must always be incubated for the full 48h.

None of the *L. ivanovii* strains yielded positive results with the SwabSURE-Listeria kit after 24h. After 48h, incubation of 9 of the *L. ivanovii* strains gave positive results with the test. At the lowest contamination level 3 strains (1122, 1128 and 1129) gave a negative result with one of the duplicate swabs and one strain (1124) was negative with both swabs. Two strains of *ivanovii* (1121 and 1125) were negative at both contamination levels.

+ = Positive (blue in colour)

- = Negative

The one strain from the exclusivity organisms which yielded a positive result with the kit was a strain of *L. seeligeri* (6603). Additional testing of strain 6603 was conducted using more dilute suspensions of the culture and even at the lowest concentration this strain still gave a positive result (Table 5). This result may not be consistent for all *L. seeligeri* strains as two (1139 and 1146) gave a negative result with the test.

+ = Positive (blue in colour)

- = Negative

The results of the sensitivity study are presented in Table 6. The test is able to yield positive results after 48h even at the lowest contamination levels tested.

CONCLUSION

The SwabSURE-Listeria kit provides a convenient ready-to-use test to confirm the potential presence of *Listeria monocytogenes* and *L. ivanovii*. Although some strains of *Listeria monocytogenes* give a positive result with the test in 24h which could be used as an early indication of contamination, it should be checked after 48h which is when all of the strains tested gave positive results. Some strains of *L. ivanovii* may fail to give a positive result with this test and some strains of *L. seeligeri* can give rise to positive results. The test provides good sensitivity and enables contamination levels below 100 cells per swab to be detected. This study demonstrated the specificity and sensitivity of the SwabSURE-Listeria kit using pure cultures. It did not assess the affect of competing or mixed populations of microorganisms on the test or the affect of environmental debris/soil, chemical residues etc which may be encountered in food production environments.

APPENDIX
Product information and instructions provided by
Technical Service Consultants Ltd.

**Pathogenic Listeria detection kit
(SwabSURE-*Listeria*)**

Test system for detection of pathogenic Listeria
from food contact and environmental surfaces

Content:

- Foam-tip swab, pre-moistened in the neutralising buffer, polyester shaft with breakpoint at 65 mm. Swab in tube, packed in the peel pouch. Product Code: TS/5-63WP (Fig.1)
- Listeria detection chromogenic medium - 1 ml in tube (Fig. 2 – prototype samples).

Principle:

- Foam swab improves recovery of contaminant microorganisms from surfaces. Neutralising buffer provides inactivation of disinfectants and chemicals reside on surfaces, and it also maintains viability of sampled microorganisms.
- Detection medium contains nutrient substrates for enriched growth of *Listeria* species; antibiotics – for suppression of non-target organisms, and chromogenic compound – for detection of pathogenic Listeria species (*L. monocytogenes* and *L. ivanovii*). Presence of *L. monocytogenes* and/or *L. ivanovii* at the concentration of ≥ 1 cell/sample results in colour change of the medium from straw-yellow to turquoise-blue.

Target organisms: *L. monocytogenes*; *L. ivanovii*

Detection level: ≥ 1 CFU/swab (internal trials)

False positive: not detected

False negative: in the presence of biocides at very high concentration

Instruction for Use:

1. Identify the site or surface for sampling. Define sampling area (e.g. by using sterile template).
2. Peel open the pouch and remove the tube.
3. Use the blue cap as a holder, remove swab from the tube and sample defined area by rubbing the swab horizontally, vertically and then diagonally for about 20 seconds across the entire area rotating the swab between thumb and index finger to ensure that the entire surface of the swab is used.
4. When sampling is completed insert swab into the tube and close tightly using the swab cap. Ensure that tube is tightly closed.
5. Record sample details on the tube label.
7. Transport samples to the laboratory as soon as possible.
8. Holding blue cap remove sampled swab from the tube, place it into diagnostic medium tube and break it into the medium (break point on the swab makes this procedure very easy). Mix by inverting the tube or using Vortex mixer.

9. Place tubes with the sampled swabs in the rack and incubate them horizontally at 37°C for 48h. Check for colour change in 24 and 48h. Change of medium colour from straw-yellow to turquoise-blue indicates presence of *L. monocytogenes* or/and *L. ivanovii*.

10. Identity of organism could be confirmed by subculturing onto selective media and further biochemical tests.
